Calcium drilling fluids are more difficult to run as most common additives adversely react with divalent ions; there are some tolerant materials available. High calcium systems, in conjunction with high temperatures and hydroaluminium silicates (clays), can form a type of cement, rendering the drilling fluid / mud irretrievably solid.

To increase the oil/water ratio, add oil. The total liquid volume will be increased by the volume of the oil added, but the water volume will not change. The 17 bbl of water now in the mud represents 25%) of the liquid volume, but it will represent only 20% of the new liquid volume. Therefore: let  $x$  = final liquid volume then,  $0.20x = 17$

In geotechnical engineering, drilling fluid, also called drilling mud, is used to aid the drilling of boreholes into the earth. Often used while drilling oil and natural gas wells and on exploration drilling rigs, drilling fluids are also used for much simpler boreholes, such as water wells. One of the functions of drilling mud is to carry cuttings out of the hole. The three main categories of drilling fluids are: water-based muds, which can be
